Share this:Q: Getting the application name from url with extension in PHP I have a website where I want to get the name of the application which is the best way to do so? I guess only since I do not have any other content other than the index.php I can get the name of the application from the url of the page using `$_SERVER['REQUEST_URI']` A: Try using the `get_current_request_uri()` function. Return the URI of the current request without an extension, for example `$_SERVER['PHP_SELF']`. The implementation is not guaranteed to follow RFC 2616, but is typically the same as `$_SERVER['REQUEST_URI']`. Used for tracking current requests by other requests when following a redirect. See also the list of available request variables in the PHP manual. Q: What is wrong with my Haskell I started learning Haskell yesterday and am working on a very simple function to swap two strings. When I tried to test it, I am getting: Couldn't match expected type 'Char' with actual type 'Int' I am thinking it is because I am entering a string as the argument but not sure. I am new so please bear with me. `swap :: Char -> Char -> Char` `swap c1 c2 | c1 == c2 = "a" | otherwise = "d"` If I remove the '|' line and just return "a", then it runs fine. I also know that I can make it a function by just declaring it to take two chars and return a string, then it works. But I am trying to learn Haskell so I want to

understand why it is not working like this. A: You want to use case in place of your conditionals. swap :: Char -> Char -> Char swap c1 c2 | c1 == c2 = "a" | otherwise = "d" If you don't use case, Haskell will use the first pattern match to return the value that is unevaluated in the case expression. That will be the type of c1, which in this case is Char and not String, and not "a". Q: What does the following statement mean? \$\$
